

Package Tracking Tool

Goal: design a simple chatbot / conversation flow which enables a user to track their package and gives them information for where to go next if they encounter any issues.

Design Choices

Prompt

PromptChain

I chose to structure the chatbot using two main classes, Prompt and PromptChain. A Prompt is an object that contains information for each prompt (message, user input validation) and is able to run itself individually by printing its message to the command line and storing user input. A PromptChain is essentially a chatbot/loop which runs a prompt then chooses the next prompt to go to.

Implementation

Prompt

- Constructor (message, validation function)
- `get_next ()` -> Prompt | callable
- `set_next (next_prompt)` -> None
 - `display ()` -> None
- `get_user_entry ()` -> str
- private method `_validate_input(self)`

PromptChain

- Constructor (start: Prompt)
- `run(self)` -> None

Extras

- Constants file w/ string messages
- main file that runs the program

Challenges & Future Work

Challenged?

- Staying within 60 minutes (went over to make it presentable)
- Fun challenge: architecting the chatbot to follow clean code principles.

| Future work might include: |

- Feature: API integration of tracking number to pull the data from USPS for package information.
- Feature: Finding nearest post office based on address and zip code using an API.
- A better user interface.
- Correct the 888 phone number to actually be a USPS agent and make the application start a call to that number.
- Integration of, for example, openAI API for better user chatbot experience.
